

The key to understanding heredity is to understand how cells divide and pass DNA information to the newly produced cells. Gregor Mendel, a 19th century amateur geneticist, was able to explain many characteristics of heredity that had mystified the professional biologists of his time. In this chapter, you will learn how to predict patterns of inheritance and how organisms pass their genetic information to future generations. Cell division processes are different between eukaryotes, prokaryotes (bacteria) and haploid gametes (eggs and sperm). Adults produce haploid gametes, with half the diploid-amount of DNA, in a slightly different way than they produce diploid cells. Yet all these cell division processes use similar proteins, as would be expected given their common evolutionary history. *{Connections: the Big Idea of Evolution is discussed explicitly in six chapters.}* The five sections of Chapter 3 focus on information at the organismal level.

Biology Learning Objectives

1. Restate the major rules and laws discovered by Gregor Mendel.
2. Analyze genetic data to demonstrate your comprehension of inheritance patterns.
3. Use diagrams to illustrate how prokaryotes reproduce through cellular fission.
4. Explain how mitosis works and its genetic outcomes.

Lecture 12 - (Preparing for) The LIVE in-person lecture

Budgeting homework time (60 min): Read and prepare for a case study on the SBE1 gene (evo-ed.org).

SBE1 case:

Read and take notes from the <http://evo-ed.com/> website in the "Pea Taste" sections: Mendel to Molecules, Cell Biol, Molecular Genet, Population Genetics. Direct link -> <http://evo-ed.com/Pages/Peas/>

Use that website as well as section 3.1 on Mendel in your textbook as resources to answer these questions. Write out your answers in your paper notebook so you can photograph and turn in one copy but keep the second one for class.

Integrating Questions

1. What are Mendel's two fundamental rules of inheritance?
2. What is an allele? How do the two alleles that determine pea seed shape/taste function?
3. Why do both the RR and Rr genotypes produce round peas?
4. We call some traits dominant and others recessive, and we relate this to their respective alleles. Explain, in terms of protein function, why some traits are expressed when alleles are heterozygous.
5. Synthesis question: Does the rr genotype result in a gain or loss of function? How could either a loss or gain of function be evolutionarily important?
6. Synthesis question: Mendel and Darwin were contemporaries, although they did not know one another. How might the principles of Mendel's laws of inheritance overlap with Darwin's theory of evolution?

1. What are Mendel's two fundamental rules of inheritance?

Law of Segregation - allele pairs separate or segregate during gamete formation + randomly unite at fertilization

4 parts. gene exist as alleles (more than one form)

- organisms inherit two alleles for each trait
- sex cells made by meiosis + allele pairs separate
- alleles can be dominant + recessive

Law of Independent Assortment -

inheritance of one characteristic is independent of another

2. What is an allele? How do the two alleles that determine ^{seed color vs flower color} pea seed shape/taste function?

R allele (round) vs. r (wrinkled) -> SBE1 gene (starch branching enzyme)

amylose -> SBE -> amylopectin inside pea seed

r allele -> SBE does not work -> amylose does not gain branches to be sticky

amylose is more like sugar small osmolytes attract more H₂O to enter pea

+ Glu + Glu = sucrose and sucrose is created then when dried get wrinkly

3. Why do both RR and Rr genotypes produce round peas?

Apparently 50% of functional SBE1 enzyme is enough to do the job

4. Dominant + recessive traits - Why are some traits expressed (as proteins) when alleles are heterozygous?

0 - if allele -> protein -> trait then if that gene is functional is expressed

5. Does rr genotype result in gain or loss of function? Evolution impact? taste sweeter now?

Loss - loss of trait could be impactful on natural selection (advantage or disadvantage?)

6. How might Mendel's Laws of inheritance overlap with Darwin's theory of evol.

Darwin could never come up with cogent "mechanism", exactly what Mendel had.

5. Synthesis question: Does the rr genotype result in a gain or loss of function? How could either a loss or gain of function be evolutionarily important?
6. Synthesis question: Mendel and Darwin were contemporaries, although they did not know one another. How might the principles of Mendel's laws of inheritance overlap with Darwin's theory of evolution?

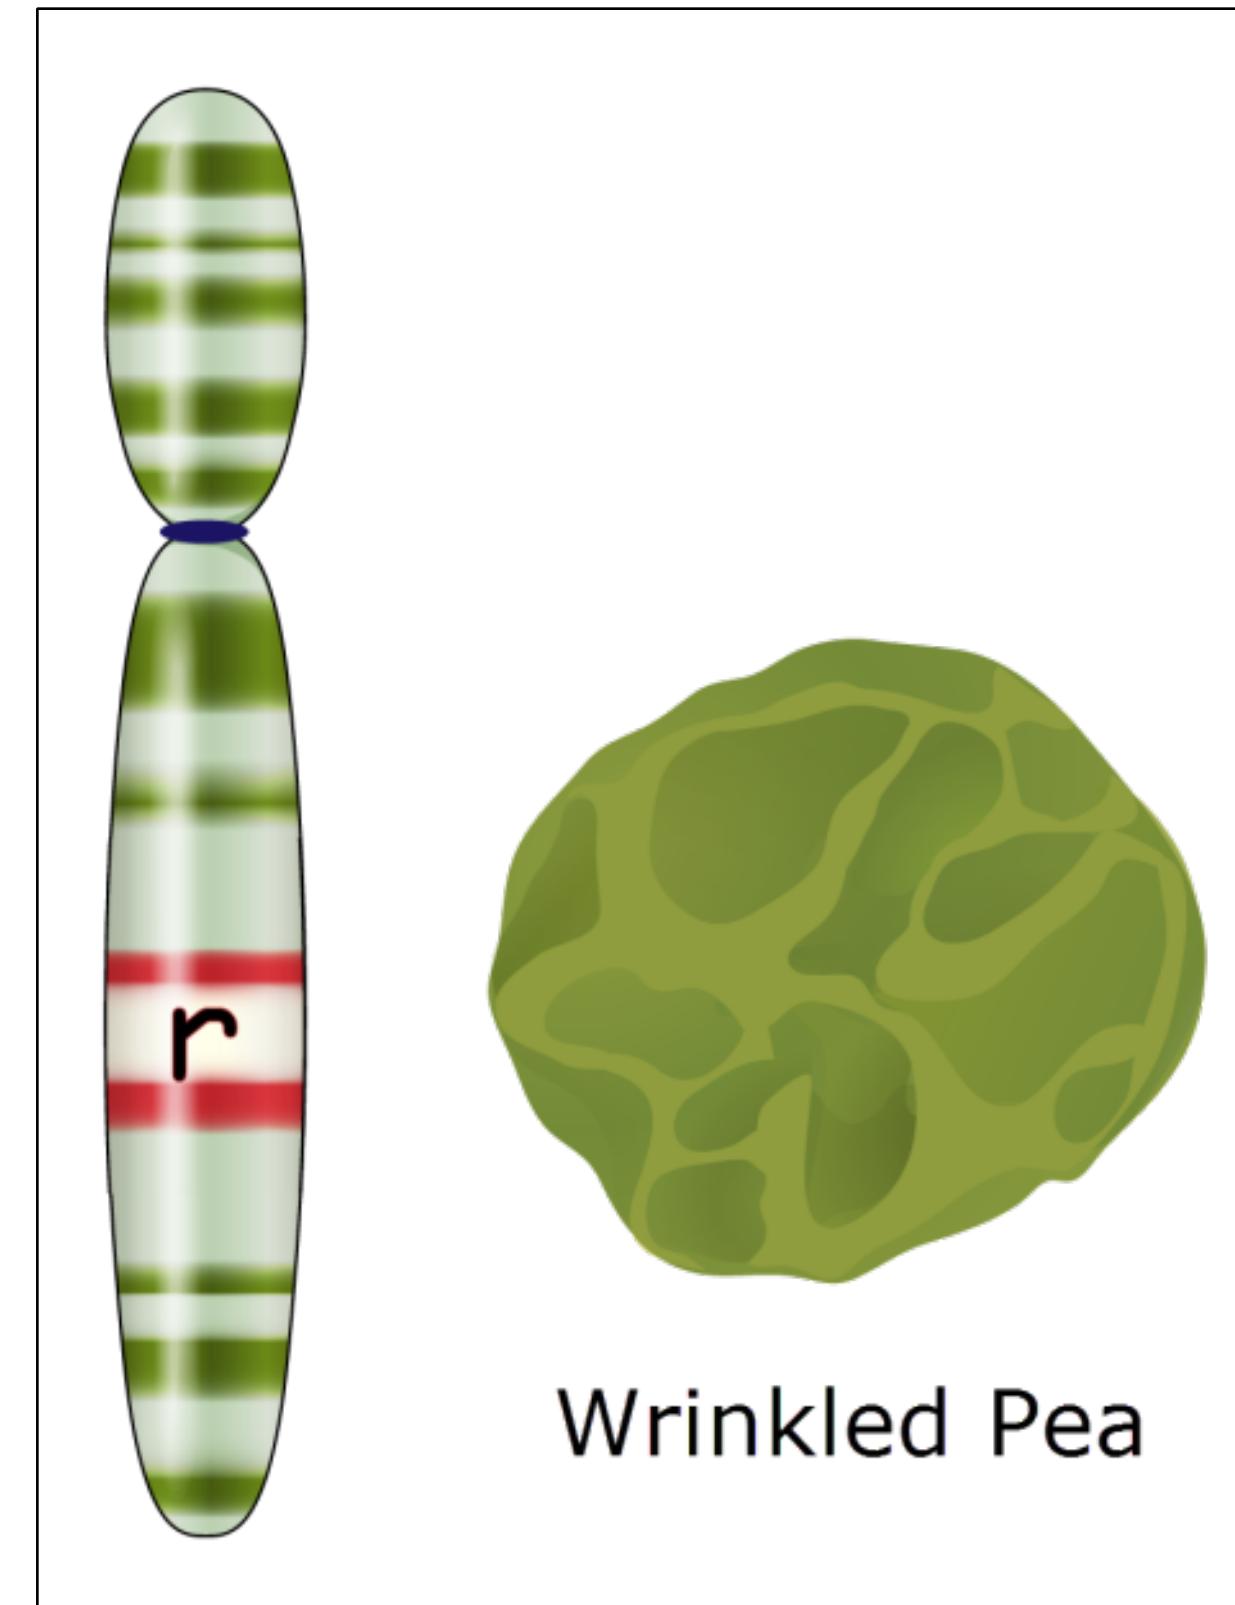

Why is R dominant over r?

Why do both the RR and Rr genotypes produce round peas?

Discuss...

At the molecular level (DNA->RNA->protein) why is that pea wrinkled?
(what might a molecular biologist predict?)

?

R= sbe1 gene

SBE= Starch Branching Enzyme

?

Codes for functional SBE1 protein.

Round Pea

This diagram shows a pea chromosome with a red band labeled 'R' on the lower arm. To its right, text states it codes for a functional SBE1 protein. Below this, a smooth, round green pea is shown, representing the dominant phenotype.

Codes for non-functional SBE1 protein.

Wrinkled Pea

This diagram shows a pea chromosome with a red band labeled 'r' on the lower arm. To its right, text states it codes for a non-functional SBE1 protein. Below this, a wrinkled green pea is shown, representing the recessive phenotype.

At the molecular level (DNA->RNA->protein) why is one pea flower white?
(what might a molecular biologist *predict*?)

?

Q: If B allele produces a purple pigment, **WHY** isn't Bb light pink (would that be blended)?

What's the GENOTYPE?

?

At the molecular level (DNA->RNA->protein) why is that pea yellow?
(what might a molecular biologist *predict*?)

?

I talked to a colleague from my old university and he said “yes, well, kinda”

Dr. Barry Starr, [Stanford University](#)

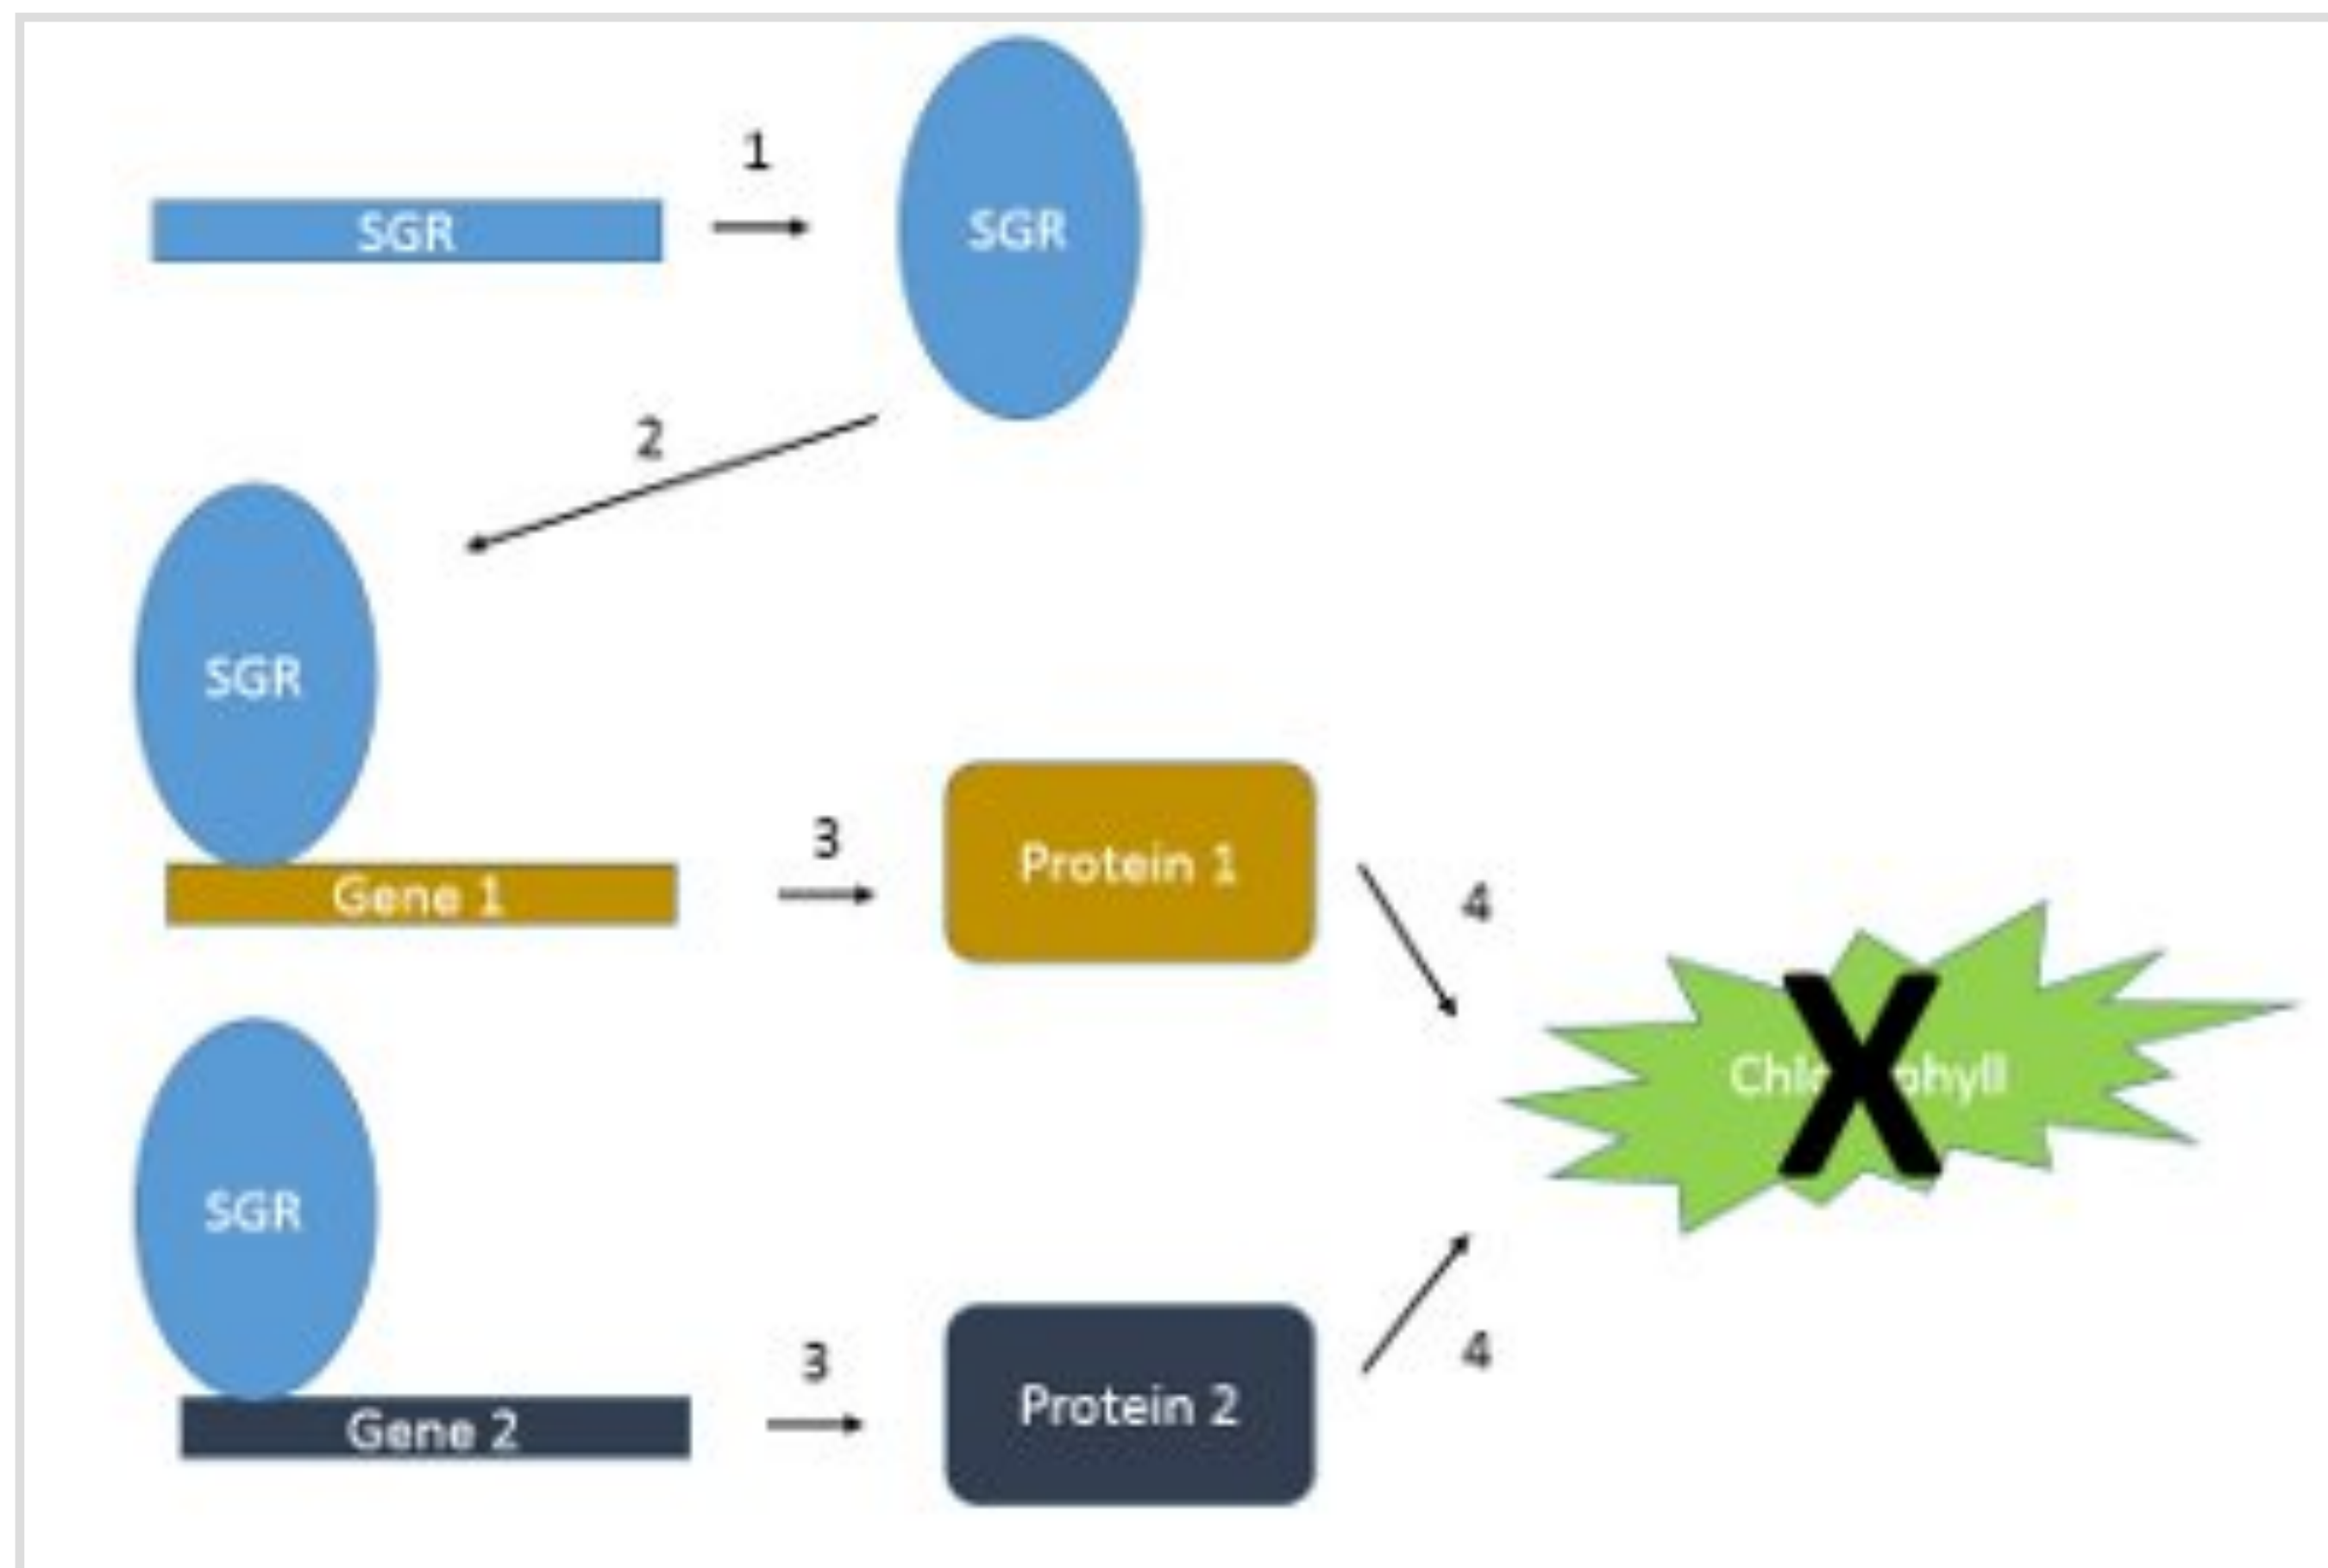

Y = SGR gene

SGR gene [blue rectangle] -makes-> SGR protein (blue oval)

?

Protein | **Protein STAY-GREEN, chloroplastic**

Gene | **SGR**

Organism | *Pisum sativum* (Garden pea)

Status | Reviewed - Annotation score: ●●●○○○ - Experimental evidence at transcript levelⁱ

Functionⁱ

Probably involved in the disassembling mechanism of the intact light-harvesting complex of photosystem II (LHCII) in the thylakoid membranes. Required for the chlorophyll breakdown pathway. Acts independent and upstream of pheophorbide a oxygenase (PAO).

Miscellaneous

Corresponds to one of the seven genes studied by Gregor Mendel in 1866 (PubMed:17204643). The green cotyledon (i) line JI2775 used in the original work has a non-functional SGR protein (AC A7VLV2) due to the presence of a two amino acids insertion (PubMed:17709752 and PubMed:18301989).

Sequenceⁱ

Sequence statusⁱ: Complete.

Sequence processingⁱ: The displayed sequence is further processed into a mature form.
